

Supplementary Figure 1. Fitted Gaussians for variant functional classification.

(a) “Abnormal” (red) and “Normal” (blue) Gaussians used to draw thresholds for classifying variants as functionally abnormal or functionally normal. Estimated density from GMM modeling is on the Y-axis, and SGE score is on the X-axis. Vertical dashed line at $X = -0.0286$ represents the upper threshold for functionally abnormal variants. Vertical dotted line at $X = -0.0197$ represents the lower threshold for functionally normal variants. (b) Strip plot of molecular consequence (Y-axis) vs. SGE score (X-axis). (c) Cumulative distribution of functional scores by molecular consequence, with the abnormal (dashed) and normal (dotted) cutoffs marked.
