

Supplementary Figure 4. Stability of the KURIS/NDD missense likelihood-ratio estimate across estimators.

Point estimates and intervals for the abnormal-class (red) and normal-class (blue) likelihood ratios computed under three estimands: the Haldane-corrected likelihood ratio (circles), the Tavtigian OddsPath (diamonds), and Bayesian posterior estimates under Beta(0.5, 0.5) and Beta(1, 1) priors (squares). For the likelihood ratio and OddsPath, the intervals shown are the log-Wald 95% confidence interval, the percentile bootstrap range, and the leave-one-out range; for the Bayesian estimand, the 95% credible interval. Shaded bands denote ACMG evidence-strength tiers, and the fraction of resamples falling in the full-data tier is annotated above each marker. Intervals extending beyond the axis are drawn with an arrowhead.
